1 Summary

1.1 General informations

This Calibration Report released by LNE-SYRTE is about the relative calibration campaign of GPS receivers located at Centre National d'Études Spatiales.

It is built according to the Annex 4 of the document "BIPM guidelines for GNSS equipment calibration", V3.2 15/02/2016, and contains all the required information, data, plots and results either required by BIPM in the frame of the CCTF Working Group on GNSS, or by BIPM and EURAMET in the frame of the Group1/Group2 calibration scheme. It also contains the uncertainty budget computation according to the Guidelines, which is showing whether the calibrated links used in the frame of the TAI computation would be in line with the conventional values.

1.2 Calibration report changes

This is Issue 1.0 of the calibration report.

3 Description of equipment and operations

The relative calibration of the GPS receiver located at CNES was organized by LNE-SYRTE with the support of local Colleagues. The reference receiver for this measurement campaign is OP71, a Septentrio PolaRx4 multichannel multi-frequencies receiver located in OP. This receiver was relatively calibrated by BIPM in the frame of a G1 calibration campaign during fall $2016 \ (\#1001-2016)$.

The traveling equipment was made of two Septentrio PolaRx4 receivers called OPM7 and OPM3, together with a Choke-Ring Ashtech antenna and a 50 m antenna cable. In CNES, the receivers to calibrate were two Septentio PolaRx4TR multi-GNSS receiver called CS21 and CS22, respectively.

All the involved equipment are described inside the BIPM information sheets provided in Annex A for all receivers and all locations. Table 1 presents a summary of the timetable and of the equipment.

CALIBRATION OF GPS RECEIVERS AT CNES

Issue 1.0. April 25, 2019

4 Data used The OP71 collected raw data are transformed into RINEX 2.11 Strata by using the UNAVCO TEQC software. The same software is also used to consert the resolution of traveling receivers into RINEX 2.11 format. Local receiver RINEX 3.03 data are provided by CNES, and converted into RINEX 2.11 format by using a software provided by GHZ. The canoration consisting in building differential pseudoranges for each code P1 and F2 between parts of receivers, these differences being corrected by the known reference (REFDLY) and antenna dable (CABDLY) delays when available. For each location, the coordinates of the antenna phase centers are especially computed for the calibration period from RINEX files by using the NRCA PPP software. The geometric correction between pairs of antenna phase centers for receivers in common-took set-up is computed by using BRDC files provided by IGS.

| Institute | Status of | MJD of | Receiver type | BIPM | RINEX |

Table 1: Summary information on the calibration trip.

As conservative estimate, the noise of the P1 and P2 differences is obtained from the highest value of the one-sigma statistical uncertainty of the TDEV at 1 d. In the case there is not enough data to compute a TDEV at 1 d, the upper limit of the last error bar available is considered as noise of the raw differences. The noise of P3 data is issued from a similar TDEV analysis.

Reference delays are measured against the local UTC(k) physical reference point at the trigger level currently used in the involved laboratories. Antenna cable delay is either obtained from dedicated measurements or included in the P1 and P2 delays when no value is available for this parameter. In this latter case, the CABDLY value is set to 0 in the parameter file.

For validation purposes, P3 CGGTTS files are computed by using the R2CGGTTS software provided by P. Defraigne (ORB), and CV are built between pairs of receivers. This is more especially the case between the two traveling receivers in each location, in order to better assess the stability of this traveling ensemble all over the calibration campaign. We have decided to consider as overestimated value for the traveling equipment stability during the campaign the upper value between the highest misclosure between the start and the end of the campaign on one side and the highest mean offset between the two traveling receivers obtained from CV on the other side.

Results of raw data processing 5

Table 2 provides a summary of the P1 and P2 delays computed from the raw differences between RINEX files, together with the REFDLY and CABDLY used for these computations. The REFDLY and CABDLY values were either measured on site or taken as known parameter for a given receiving chain. Table 2 also includes the P1 and P2 internal delays of traveling equipment as computed against OP71, in average between the start and the end of the campaign, with the related REFDLY when located in remote stations. From our point of view, this table is the most comprehensive summary of the calibration campaign.

In addition, the Table 3 is providing the raw difference (Rawdiff) values as required by reference [1]. All the plots of P1 and P2 computed delays and of the related TDEV analysis are provided in Annex B. The P3 CV computed by using the results of the calibration and the related DEV analysis are also made available in Annex B.

6.2 Visited systems with respect the traveling system

Table 5 is providing the computed internal delays INTDLY P1 and P2 for the visited systems by using OPM7 and OPM3 as reference systems. In addition, it also provides the differences between both traveling receivers, allowing for a monitoring of the stability of traveling equipment during the whole campaign.

When applying these delays for computing CGGTTS P3 CV between CS21, respectively CS22, and OPM3 and OPM7, we note an unexpected diurnal term of significant amplitude. In addition the diurnal of CS21 seems larger by a factor of about 2 compared to the diurnal of CS22.

| Pair | MJD of measurement | INTDLY P1 | INTDLY P2 | P1 -P2 |
|--------------|--------------------|-----------|-----------|--------|
| OPM7-CS21 | 58284 - 58298 | 58.585 | 56.682 | 1.903 |
| OPM3-CS21 | 58284 - 58298 | 58.509 | 56.581 | 1.928 |

6.3 Uncertainty estimation

We provide in this section an estimation of the uncertainty of the differential calibration for the receivers at CNES. All the uncertainty budgets have been built according to the reference [1] in order to provide the required u_{CAL0} values. The details on the systematic uncertainties are provided in Annex C. Note that we have chosen as u_b for misclosure the upper values between the actual misclosure between the start and the end of the campaign and the offset between both traveling equipment.

| Uncertainty | Value P1 | Value P2 | Value | Value P3 | Description |

7 Final results for the system to calibrate

Table 8 is providing the final results of this calibration campaign, by following the BIPM Guidelines. In addition, Table 9 is providing the computed conservative k = 2 expanded uncertainties in order to be in line with EURAMET recommendations. The CNES calibrated link used in the frame of the TAI computation is in line with the conventional combined uncertainty of 2.5 ns.
